## Design for importing data into a data warehouse

This document contains design principles for implementation of the vehicle's usage data ETL process into the data warehouse.

#### 1. Basic Architecture

Tools chosen for the implementation:

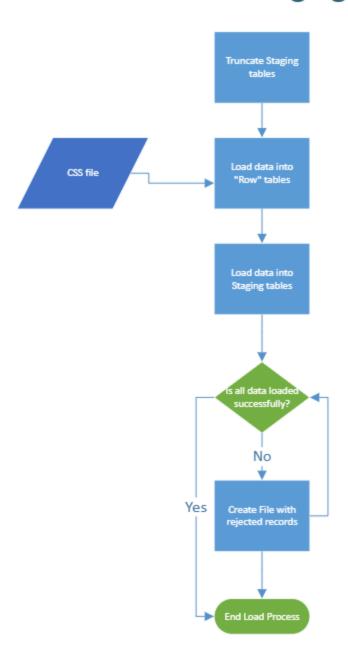

- SQL Server for DW database
- SSIS for data loading from CSS files into the staging database
- DML for populating reporting database from staging

#### 2. Pipelines

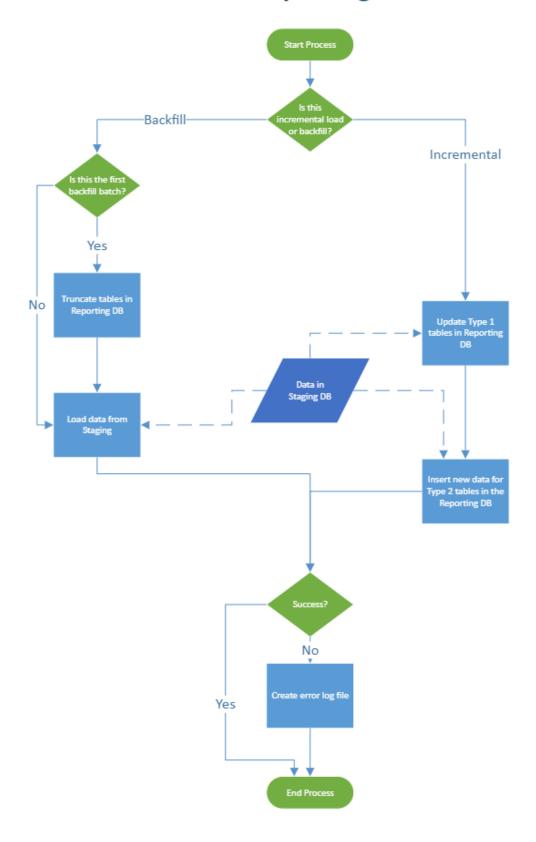

Below are the flowcharts for 2 processes: initial loading into the Staging database, and data load from Staging to Reporting.

# **Load Into Staging database**

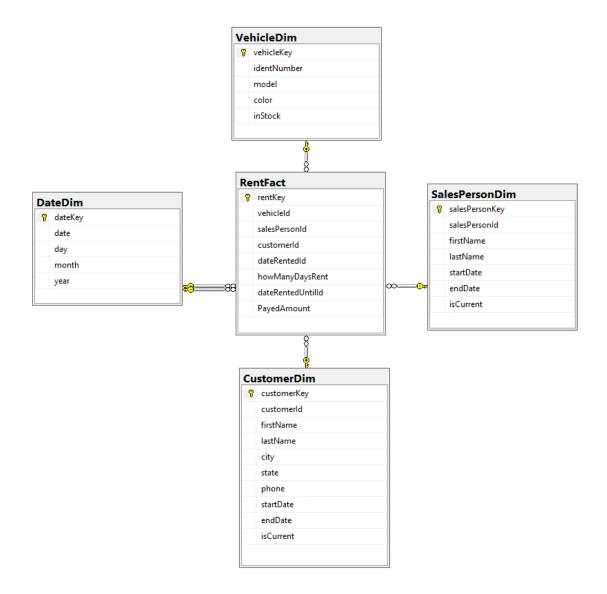

"Row" tables are historical tables that contain row data from CSS files (they are optional).

# **Load Into Reporting database**

# 3. Example of Data Model

# 4. Example of Data Load and Transformation

This is an example of data load and transformation from Customer CSV file into the Staging database, and into Reporting database.

| CSV File: Customer                      |
|---|
| 1003, Bob, Martin, Austin, TX, 512-487- |
| 7777                                    |

#### **Staging DB**

| Customer  |          |  |
|-----------|----------|--|
| id        | 1003     |  |
| firstName | Bob      |  |
| LastName  | Martin   |  |
| City      | Austin   |  |
| State     | TX       |  |
|           | 512-487- |  |
| Phone     | 7777     |  |

| Customer_IdLookup |          |  |
|-------------------|----------|--|
| sourceType        | CSV      |  |
| source            | Customer |  |
| id                | 1003     |  |
| dwKey             | 205      |  |

#### Reporting DB before ETL

| Customer    |            |  |
|-------------|------------|--|
| customerKey | 20005      |  |
| customerId  | 205        |  |
| firstName   | Bob        |  |
| lastName    | Martin     |  |
| city        | Austin     |  |
| state       | TX         |  |
| phone       | 5122582457 |  |
| startDate   | 5/1/2010   |  |
| endDate     | 12/31/2099 |  |
| isCurrent   | 1          |  |

#### **Reporting DB after ETL**

| Customer    |            |            |
|-------------|------------|------------|
| customerKey | 20005      | 38025      |
| customerId  | 205        | 205        |
| firstName   | Bob        | Bob        |
| lastName    | Martin     | Martin     |
| city        | Austin     | Austin     |
| state       | TX         | TX         |
| phone       | 5122582457 | 5124877777 |
| startDate   | 5/1/2010   | 2/10/2021  |
| endDate     | 2/9/2021   | 12/31/2099 |
| isCurrent   | 0          | 1          |

## 5. Performance and scalability considerations

- Consider a mix of rowstore and columnstore indexes for performance benefit
- Partitioning big tables and views for performance
- Use fast storage
- Replication, High Availability groups, clustering in SQL Server
- Use linked servers for executing distributed queries
- Using middleware to route queries to correct database if DW is broken down into several databases (ex. US location, Europe etc.)

### 6. Security considerations

Login with read/write permissions on the tables in Staging and Reporting DBs for ETL process

- Login with read/delete files permissions in the file system where CSV files, archived CSV file and log files are located
- Encryption of sensitive information in the DB
- Roles for BI users with read permissions in Reporting DB on only data that they need

### 7. Monitoring and alerting

- Log files, and files with rejected records created during ETL
- Email on errors during ETL
- GUI application where ETL status, errors and warnings can be displayed
